

Tutorial 4 1/2: Workflow diagrams

In this tutorial, we'll review some key concepts on workflow diagrams and then show some solved examples.

Index

1. Brief introduction

1.1. Why workflow diagrams?

1.2. What do all workflow diagrams need to have?

2. Symbols recap

3. A little advice

4. Examples

4.1. Image processing

4.2. Clustering algorithm

1. Brief introduction

1.1. Why workflow diagrams?

They allow us to solve a problem without having to worry about all the syntactic difficulties of programming languages (e.g. "==" instead of "="), while making the process comprehensible to others.

Moreover, when done right, they show that a person actually knows how to handle a programming task.

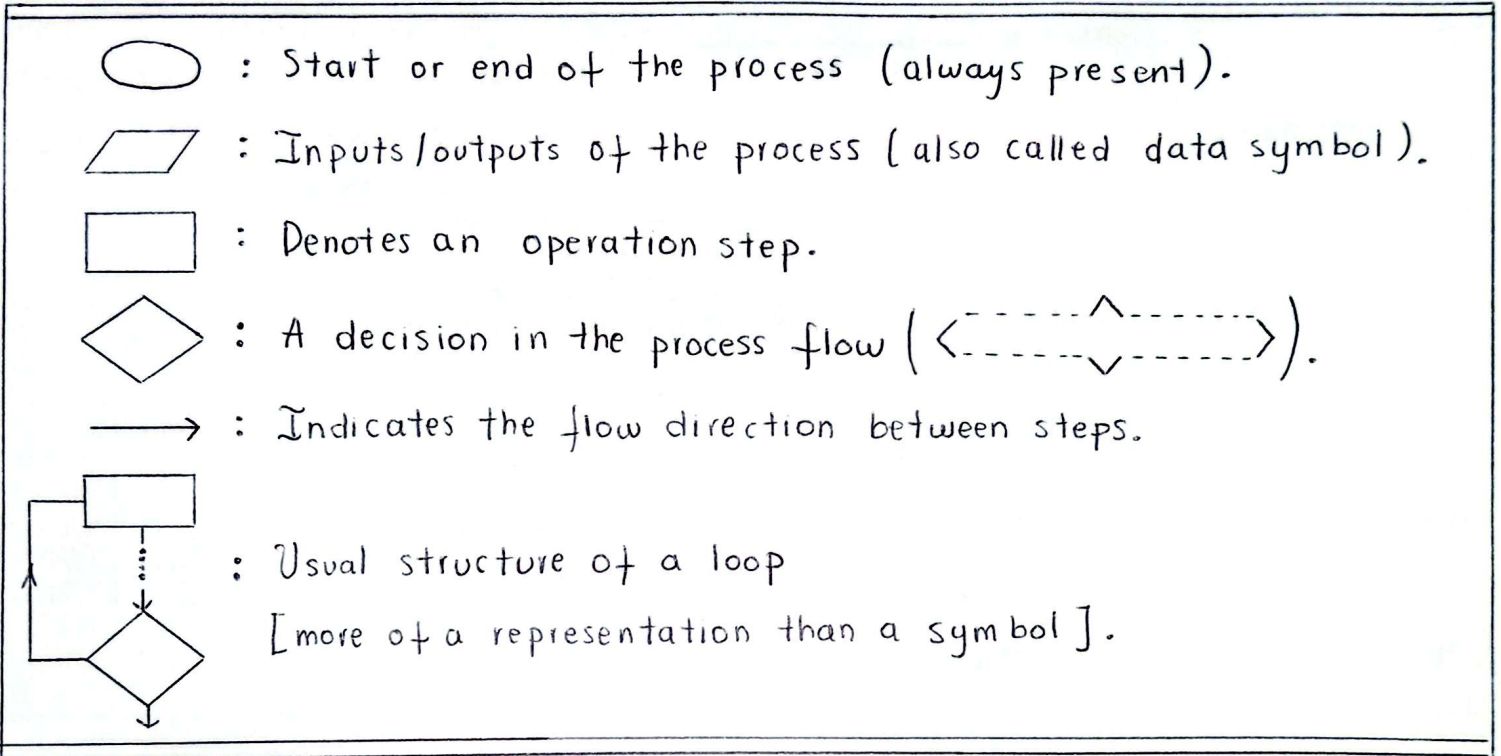

1.2. What do all workflow diagrams need to have?

At a fundamental level, two things: what and how.

- What: Data, variables and features to use.
- How: Tools and methods (functions: self-made or third-party) to be applied on the what.

2. Symbols recap

We'll keep it simple.

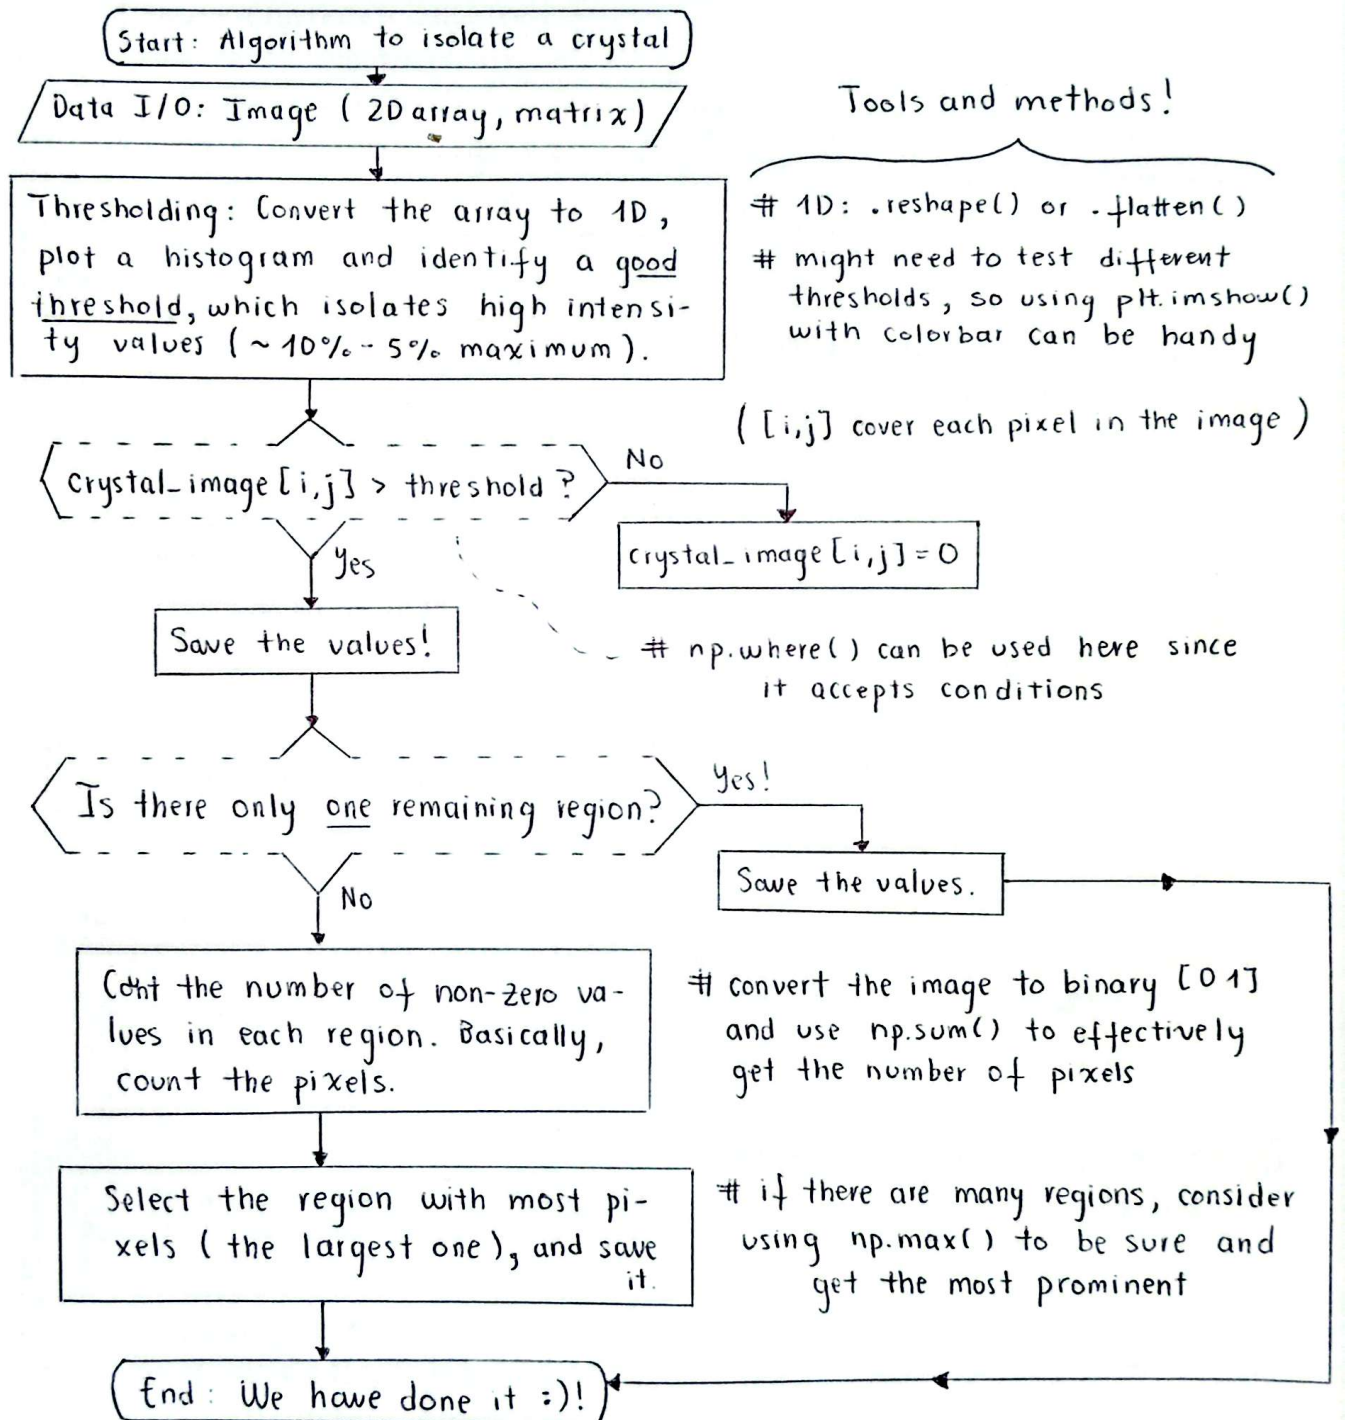

3. A little advice

To start, all you need is an idea 😊. It does not have to be a great one, just one that, in principle, should work. I wouldn't recommend starting to write without having that. So take your time and don't rush :).

4. Examples

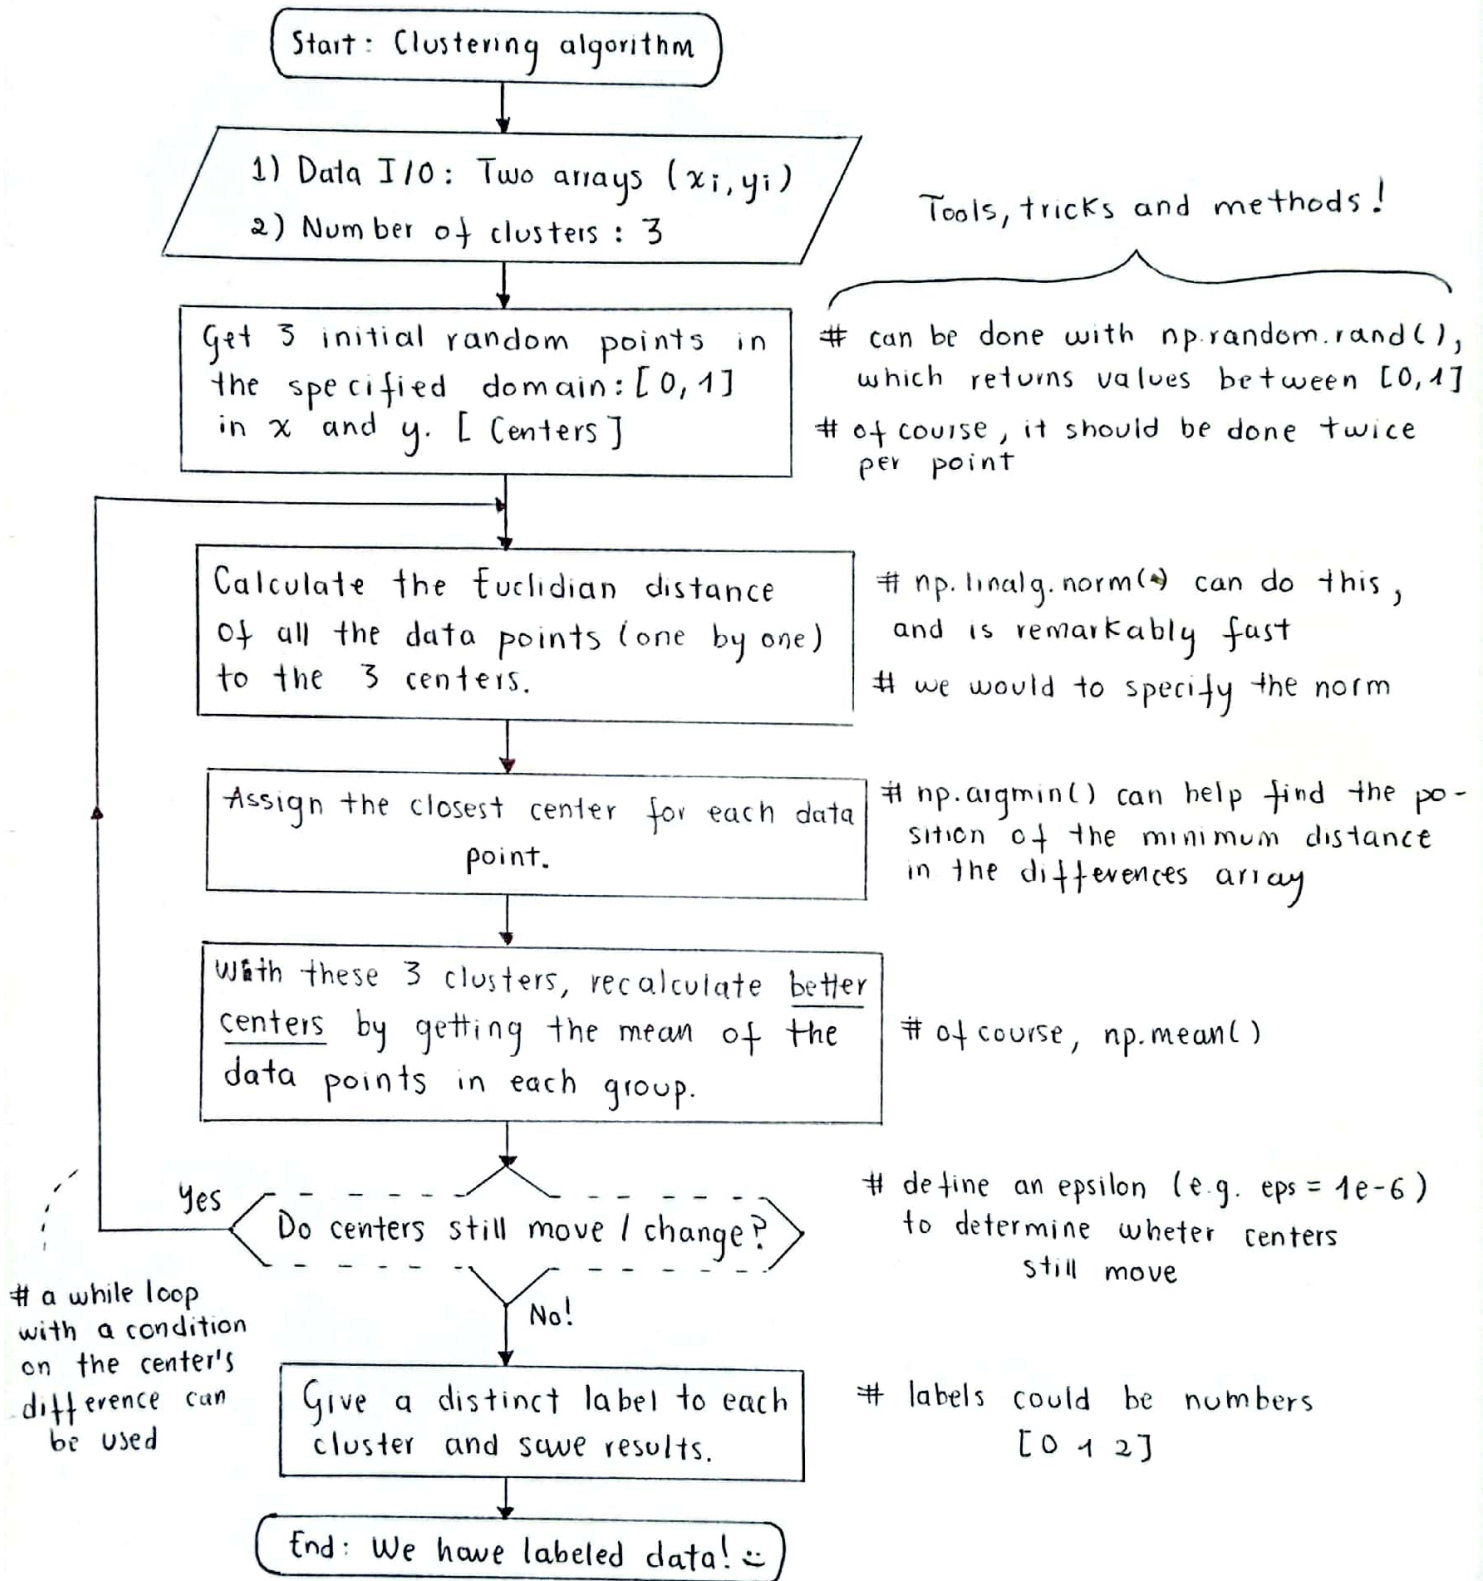

4.1. Image processing: Imagine you obtain a photograph of iron crystals (small scale), and you're asked to isolate the most prominent crystal from both the background and the rest of the image.

Comment: Britney Robalino Ramirez helped me with HER solution. Small things were added.

4.2. Clustering algorithm [from my Special-topics class]

Given the following distribution of points, how would you add a distinct label to each of the seemingly 3 groups? So that points with the same label belong to the same group.

Final comment: That'd be it. Sorry, I don't think any of the smiley faces looks pretty enough.
